Dr Renata Borovica-Gajic*

Lecture 17
Transactions

Week 9

slides adopted from David Eccles

Today's Session…

- Why we need user-defined transactions
- Properties of transactions
- How to use transactions
- Concurrent access to data
- Locking and deadlocking
- Transaction recovery

What is a (database) transaction?

- A logical unit of work that must either be *entirely* completed or aborted (indivisible, atomic)

  eg: transfer money from one account to another

- DML statements are already atomic
- DBMS also allows for *user-defined* transactions
- These are a sequence of DML statements, such as:
  - a series of UPDATE statements to change values
  - a series of INSERT statements to add rows to tables
  - DELETE statements to remove rows

  fully execute successfully or cancel everything

- A successful transaction changes the database from one consistent state to another
  - All data integrity constraints are satisfied

Transaction Properties (ACID)

- Atomicity (All or nothing)
  - A transaction is treated as a single, indivisible, logical unit of work. All operations in a transaction must be completed; if not, then the transaction is aborted
- Consistency
  - Constraints that hold before a transaction must also hold after it
  - multiple users accessing the same data see the same value
- Isolation
  - Changes made during execution of a transaction cannot be seen by other transactions until this one is completed
- Durability
  - When a transaction is complete, the changes made to the database are permanent, even if the system fails

Why do we need transactions?

- Transactions solve TWO problems:

  1. users need the ability to define a unit of work

  2. concurrent access to data by >1 user or program

Problem 1: Unit of work

- Single DML or DDL command (implicit transaction)
  - Changes are "all or none"
  - **Example**:
    - Update 700 records, but DBMS crashes after 200 records processed
    - Restart server -- you will find no changes to *any* records

- Multiple statements (user-defined transaction)

```
START TRANSACTION;  (or, 'BEGIN')
    SQL statement;
    SQL statement;
    SQL statement;
    ...
COMMIT;    (commits the whole transaction)
    Or ROLLBACK (to undo everything)
```

- SQL keywords: **begin, commit, rollback**

Business transactions as units of work

- Each transaction consists of several SQL statements, embedded within a larger application program
- Transaction needs to be treated as an indivisible unit of work
- “Indivisible” means that either the whole job gets done, or none gets done: if an error occurs, we don’t leave the database with the job half done, in an inconsistent state

In the case of an error:

- Any SQL statements already completed must be reversed
- Show an error message to the user
- When ready, the user can try the transaction again
- This is briefly annoying – but inconsistent data is disastrous

THE UNIVERSITY OF MELBOURNE

Demo: Transaction as unit of work

- Demonstrate Transactions
  - CRE_ACCOUNT TXN_ACCOUNT on LMS resources

```
-- Transaction;
 START TRANSACTION; -- An explicit start - but after any commit a NEW transaction begins

-- Statement 2
 SELECT * FROM ACCOUNT;

--  (declare a temporary variable amount persistent for this session)
 set @amount = 100;

-- Statement 3

 UPDATE ACCOUNT set balance = balance - @amount where id =1;

-- Statement 4 confirm deduction from savings but not yet deposited to credit
 SELECT * FROM ACCOUNT;

--  Statement 5 deposit the amount into the credit account
 UPDATE ACCOUNT set balance = balance + @amount where id = 2;

-- Statement 6 confirm all changes
 SELECT * FROM ACCOUNT;

-- Statement 7 EXPLICIT COMMIT;
 COMMIT;

-- ALL CHANGES PERMANENT CAN NOT BE UNDONE WITH ROLLBACK
```

if commit, can't roll back

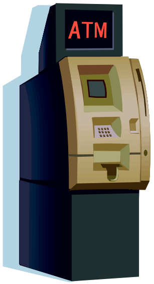
Problem 2: Concurrent access

- What happens if we have multiple users accessing the database at the same time? (this is reality)
- Concurrent execution of DML against a shared database
- Note that the sharing of data among multiple users is where much of the benefit of databases comes from – users communicate and collaborate via shared data

- But what could possibly go wrong?
  - lost updates
  - uncommitted data
  - inconsistent retrievals

The Lost Update problem

Alice



Read account balance (balance = $1000) | Withdraw $100 (balance = $900) | Write balance balance = $900

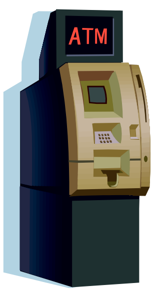
inconsist

Time

t1a t2a t3a

t1b t2b t3b

Bob



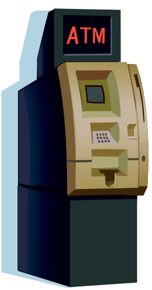
Read account balance (balance = $1000) | Withdraw $800 (balance = $200) | Write balance balance = $200

Balance should be $100

The Uncommitted Data problem

- Uncommitted data occurs when two transactions execute concurrently and the first is rolled back after the second has already accessed the uncommitted data

Alice



Bob

Time

t1 Read balance (balance = $1000)

t2 Withdraw $800 (balance = $200)

t3 Read balance (balance = $200)

t4 Rollback balance = $1000

t5 Withdraw $100 (balance = $100)

t6 Write balance balance = $100

Balance should be $900

The Inconsistent Retrieval problem

- Occurs when one transaction calculates some aggregate functions over a set of data, while other transactions are updating the data
  - Some data may be read after they are changed and some before they are changed, yielding *inconsistent* results

Alice	Bob
SELECT SUM(Salary) FROM Employee;	UPDATE Employee SET Salary = Salary * 1.01 WHERE EmpID = 33;
	UPDATE Employee SET Salary = Salary * 1.01 WHERE EmpID = 44;
(finishes calculating sum)	COMMIT;

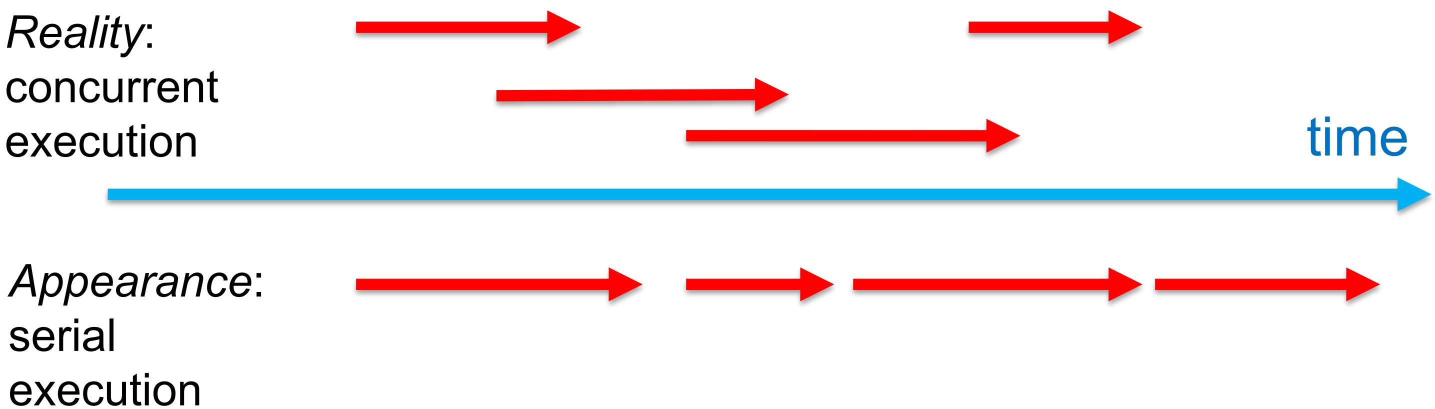
Example: Inconsistent Retrieval

Time	Trans-action	Action	Value	T1 SUM	Comment
1	T1	Read Salary for EmpID 11	10,000	10,000	
2	T1	Read Salary for EmpID 22	20,000	30,000	
3	T2	Read Salary for EmpID 33	30,000		
4	T2	Salary = Salary * 1.01			
5	T2	Write Salary for EmpID 33	30,300		
6	T1	Read Salary for EmpID 33	30,300	60,300	*after* update
7	T1	Read Salary for EmpID 44	40,000	100,300	*before* update
8	T2	Read Salary for EmpID 44	40,000		
9	T2	Salary = Salary * 1.01			
10	T2	Write Salary for EmpID 44	40,400		
11	T2	COMMIT			
12	T1	Read Salary for EmpID 55	50,000	15[illegible]	
13	T1	Read Salary for EmpID 66	60,000	210,300	

we want either
before $210,000
or
after $210,700

Serializability

- Transactions ideally are "serializable"
  - Multiple, concurrent transactions *appear as if* they were executed one after another
  - Ensures that the concurrent execution of several transactions yields consistent results



but true serial execution (i.e. no concurrency) is very expensive!

Concurrency control methods

- To achieve efficient execution of transactions, the DBMS creates a *schedule* of read and write operations for concurrent transactions
- Interleaves the execution of operations, based on concurrency control algorithms such as *locking* or *time stamping*
- Several methods of achieving concurrency control
  - Locking ← Main method used
  - Time stamping
  - Optimistic Concurrency Control

  } Alternatives

Concurrency Control with Locking

- Lock:
  - Guarantees exclusive use of a data item to a current transaction
    - T1 acquires a lock prior to data access; the lock is released when the transaction is complete
    - T2 does not have access to data item currently being used by T1
    - T2 has to wait until T1 releases the lock
  - Required to prevent another transaction from reading inconsistent data
- Lock manager
  - Responsible for assigning and policing the locks used by the transactions

- Question: at what granularity should we apply locks?

Lock Granularity Options 1/2

- Database-level lock
  - Entire *database* is locked
  - Good for batch processing but unsuitable for multi-user DBMSs
  - T1 and T2 can not access the same database concurrently even if they use different tables
  - Examples: SQLite, Access
- Table-level lock
  - Entire *table* is locked - as above but not quite as bad
  - T1 and T2 can access the same database concurrently as long as they use different tables
  - Can cause bottlenecks, even if transactions want to access different parts of the table and would not interfere with each other
  - Not suitable for highly multi-user DBMSs

Lock Granularity Options 2/2

- Page-level lock
  - An entire *disk page* is locked
  - Not commonly used now
- Row-level lock
  - Allows concurrent transactions to access *different rows* of the same table, even if the rows are located on the same page
  - Improves data availability but with high overhead (each row has a lock that must be read and written to)
  - Currently the most popular approach (MySQL, Oracle)
- Field-level lock
  - Allows concurrent transactions to access the same row, as long as they access different attributes within that row
  - *Most flexible* lock but requires an extremely high level of overhead
  - Not commonly used

Types of Locks

- Binary Locks
  - Has only two states: locked (1) or unlocked (0)
  - Eliminates "Lost Update" problem
    - the lock is not released until the statement is completed
  - Considered too restrictive to yield optimal concurrency, as it locks even for two READs (when no update is being done)

    should allow reading

- The alternative is to allow both Shared and Exclusive locks
  - Often called Read and Write locks (discussed next)

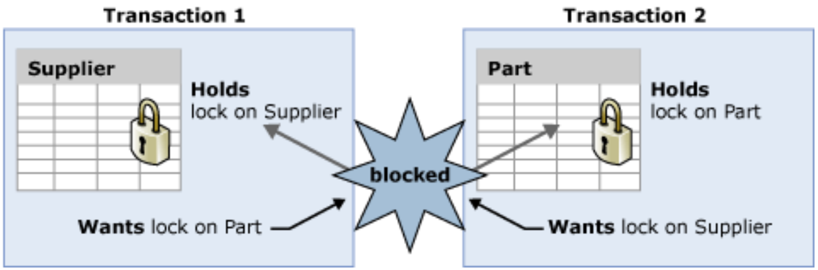
Shared and Exclusive Locks

- Exclusive lock
  - Access is reserved for the transaction that locked the object
  - Must be used when transaction intends to WRITE
  - Granted if and only if *no other locks* are held on the data item
  - In MySQL: “select … for update”

- Shared lock
  - Other transactions are also granted Read access
  - Issued when a transaction wants to READ data, and no Exclusive lock is held on that data item
    - Multiple transactions can each have a shared lock on the same data item if they are all just reading it
  - In MySQL: “select … for share”

Deadlock

- Condition that occurs when two transactions wait for each other to unlock data
  - T1 locks data item X, then wants Y
  - T2 locks data item Y, then wants X
  - Each waits to get a data item which the other transaction is already holding
  - Could wait forever if not dealt with
- Only happens with exclusive locks
- Deadlocks are dealt with by:
  - Prevention
  - Detection
  - (we won't go into details)



THE UNIVERSITY OF MELBOURNE

Deadlock demo

deccles2 — mysql -u root -p — 80×24

```
Reading table information for completion of table and column names
You can turn off this feature to get a quicker startup with -A

Database changed
mysql> SELECT * FROM DEPT;
+--------+------------+----------+
| deptno | name       | location |
+--------+------------+----------+
|     10 | ACCOUNTING | NEW YORK |
|     20 | RESEARCH   | DALLAS   |
|     30 | SALES      | CHICAGO  |
|     40 | OPERATIONS | BOSTON   |
+--------+------------+----------+
4 rows in set (0.00 sec)
```

1
```
mysql> UPDATE DEPT set location = 'SYDNEY' where deptno = 30;
Query OK, 1 row affected (0.08 sec)
Rows matched: 1  Changed: 1  Warnings: 0
```

3
```
mysql> UPDATE DEPT set location = 'MELBOURNE' where deptno = 20;
Query OK, 1 row affected (13.07 sec)
Rows matched: 1  Changed: 1  Warnings: 0

mysql> 
```

deccles2 — mysql -u root -p — 71×24

```
mysql> USE SCOTT;
Reading table information for completion of table and column names
You can turn off this feature to get a quicker startup with -A

Database changed
mysql> SELECT * FROM DEPT;
+--------+------------+----------+
| deptno | name       | location |
+--------+------------+----------+
|     10 | ACCOUNTING | NEW YORK |
|     20 | RESEARCH   | DALLAS   |
|     30 | SALES      | CHICAGO  |
|     40 | OPERATIONS | BOSTON   |
+--------+------------+----------+
4 rows in set (0.00 sec)
```

2
```
mysql> UPDATE DEPT set location = 'AUCKLAND' WHERE deptno = 20;
Query OK, 1 row affected (0.00 sec)
Rows matched: 1  Changed: 1  Warnings: 0
```

4
```
mysql> Update dept set location = 'WELLINGTON' where deptno = 30;
ERROR 1213 (40001): Deadlock found when trying to get lock; try restart
ing transaction
mysql> 
```

- Two separate sessions
- In order:

1. Tx1 Update row 3 (Green)
2. Tx2 Update row 2 (White)
3. Tx3 Update row 2 (Green)
4. Tx4 Update row 3 (White)

- Note: Only the session which detects the deadlock rolls back the transaction. The Green session still holds locks on row 2 and 3

Alternative concurrency control methods

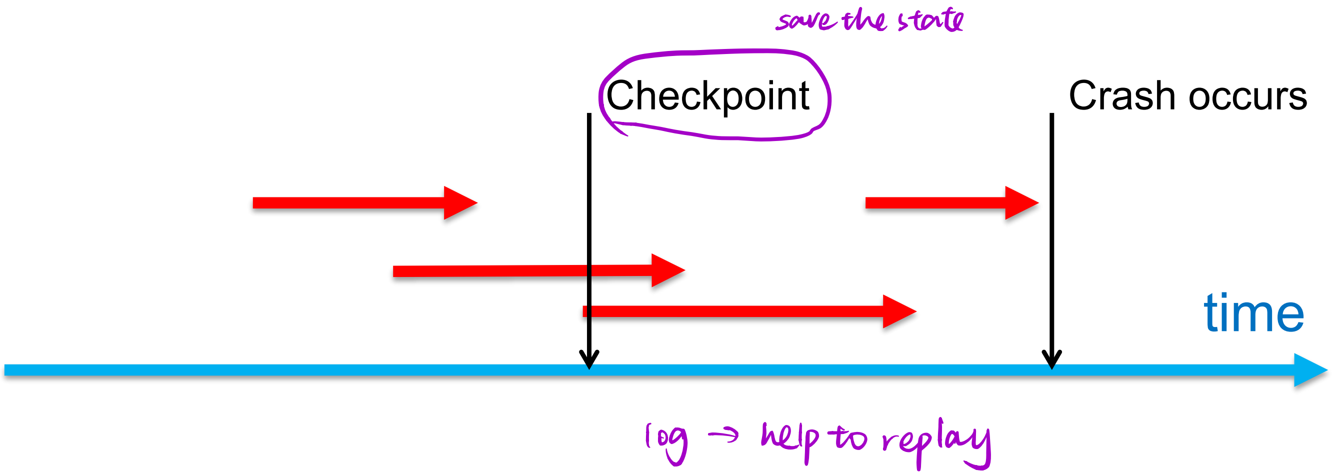
- Timestamp
  - Assigns a global unique timestamp to each transaction
  - Each data item accessed by the transaction gets the timestamp
  - Thus for every data item, the DBMS knows which transaction performed the last read or write on it
  - When a transaction wants to read or write, the DBMS compares its timestamp with the timestamps already attached to the item and decides whether to allow access
- Optimistic
  - Based on the assumption that the majority of database operations *do not* conflict
  - Transaction is executed without restrictions or checking
  - Then when it is ready to commit, the DBMS checks whether any of the data it read has been altered – if so, rollback

Logging transactions

- Allow us to restore the database to a previous consistent state
- If a transaction cannot be completed, it must be aborted and any changes rolled back
- To enable this, DBMS tracks *all* updates to data
- This *transaction log* contains:
  1. A record for the beginning of the transaction
  2. For each SQL statement
     - operation being performed (update, delete, insert)
     - objects affected by the transaction
     - "before" and "after" values for updated fields
     - pointers to previous and next transaction log entries
  3. The ending (COMMIT) of the transaction

Transaction log

- Also provides the ability to restore a corrupted database
- If a system failure occurs, the DBMS will examine the log for all uncommitted or incomplete transactions and it will restore the database to a previous state



Example transaction log

TRL ID	TRX NUM	PREV PTR	NEXT PTR	OPERATION	TABLE	ROW ID	ATTRIBUTE	BEFORE VALUE	AFTER VALUE
341	101	Null	352	START	****Start Transaction				
352	101	341	363	UPDATE	PRODUCT	54778-2T	PROD_QOH	45	43
363	101	352	365	UPDATE	CUSTOMER	10011	CUST_BALANCE	615.73	675.62
365	101	363	Null	COMMIT	**** End of Transaction				
397	106	Null	405	START	****Start Transaction				
405	106	397	415	INSERT	INVOICE	1009			1009,10016, ...
415	106	405	419	INSERT	LINE	1009,1			1009,1, 89-WRE-Q,1, ...
419	106	415	427	UPDATE	PRODUCT	89-WRE-Q	PROD_QOH	12	11
423				CHECKPOINT					
427	106	419	431	UPDATE	CUSTOMER	10016	CUST_BALANCE	0.00	277.55
431	106	427	457	INSERT	ACCT_TRANSACTION	10007			1007,18-JAN-2004, ...
457	106	431	Null	COMMIT	**** End of Transaction				
521	155	Null	525	START	****Start Transaction				
525	155	521	528	UPDATE	PRODUCT	2232/QWE	PROD_QOH	6	26
528	155	525	Null	COMMIT	**** End of Transaction				
						***** C *R*A* S* H ****			

What is examinable

- Why do we need transactions?
- What is a transaction?
- ACID (properties of ACID) atomicity consistency isolation durability
- Locking levels & types including deadlock scenario
  - Exclusive and Shared Locks
- Concurrency
  - Being able to demonstrate concurrency
- Concurrency Issues
  - (Lost update, uncommitted changes, inconsistent retrieval)
- Logging

Next lecture
